Abstract—The purpose of this study was to determine the effect of a 10-week training program on the heart rate (HR) and heart rate reserve (HRR) of sedentary middle-aged men. The subjects were randomly assigned to a control group (CG) and an exercise group (EG). The EG performed a 10-week training program consisting of 3 sessions per week. The HR and HRR were measured at rest and during submaximal and maximal exercise at baseline and after 10 weeks. The results showed that the EG had a significant decrease in HR at rest and during submaximal and maximal exercise compared to the CG. The HRR also showed a significant increase in the EG compared to the CG. The results suggest that a 10-week training program can improve the cardiovascular fitness of sedentary middle-aged men.

- Day and night temperatures that are longer than the standard atmospheric conditions will negatively affect the rate of soil moisture evaporation, especially during the night, that are far below the average temperature for the season of the forest.
- Increased moisture in the soil will negatively affect the rate of soil moisture evaporation, the length of the season may be extended depending on the soil moisture characteristics.
- The soil moisture evaporation rate depends on the way the surface of the forest is covered. The presence of a protective forest floor, especially a snow layer, is not suitable for these periods of increased evaporation. Snowfall, however, is not a problem for the forest (as a rule).
