

Keystone Species

Saguaro Cactus

What is a keystone species?

A keystone species is a species that has a disproportionately large effect on its environment relative to its abundance. The concept was developed by ecologist Robert Paine in 1969, based on his work with intertidal invertebrates. The term "keystone" is derived from the keystone of an arch, which is the central, topmost stone that holds the entire structure together.

Keystone species play a critical role in maintaining the structure of an ecosystem, and their removal can lead to significant changes in the ecosystem's composition and function. For example, the removal of a keystone predator can lead to an increase in the number of its prey, which can in turn lead to a decrease in the number of other species in the ecosystem.

Why is the Saguaro a keystone species?

The Saguaro cactus is a keystone species in the Sonoran Desert. It provides food and shelter for a wide variety of animals, including birds, lizards, and snakes. The cactus also plays a role in the desert's water cycle, as it stores water in its thick, fleshy stems. This water is then released into the soil, where it can be used by other plants and animals.
