

Keystone Species

Saguaro Cactus

What is a keystone species?

A keystone species is a species that has a disproportionately large effect on its environment relative to its abundance. The concept was developed by ecologist Robert Paine in 1969, based on his studies of intertidal rocky shore communities. The term "keystone" is derived from the keystone of an arch, which is the central, topmost stone that holds the entire structure together.

Keystone species can be found in many different ecosystems, from marine environments to terrestrial ones. They can be predators, such as wolves in a forest, or engineers, such as beavers in a river. The removal of a keystone species can lead to significant changes in the structure and function of an ecosystem.

Why is the Saguaro a keystone species?

The Saguaro cactus is a keystone species in the Sonoran Desert. It provides food and shelter for many animals, including birds, lizards, and snakes. The cactus also plays a role in the water cycle, storing water in its thick stems and releasing it slowly over time. Without the Saguaro, the desert ecosystem would be very different.
