

# Real-World Ecology Analysis

## Experiment 1a: During the Ice Age

Mathematically modeling an ecological system requires a complex understanding of the system's structure and the interactions between its components. In this experiment, we will analyze a real-world ecological system during the Ice Age, focusing on the interactions between different species and the environment. The system is modeled using a set of differential equations that describe the changes in the population of different species over time. The model is based on the following assumptions:

- The system is a closed system, meaning that no individuals enter or leave the system.
- The population of each species is represented by a vector  $\mathbf{x}$ , where  $x_i$  is the population of species  $i$ .
- The interactions between species are represented by a matrix  $\mathbf{A}$ , where  $A_{ij}$  is the interaction between species  $i$  and  $j$ .
- The environment is represented by a vector  $\mathbf{e}$ , where  $e_i$  is the value of the  $i$ -th environmental variable.

The model is solved using a numerical method, and the results are plotted against time. The plot shows the population of each species over time, as well as the values of the environmental variables. The results show that the population of each species changes over time, and that the environmental variables also change. The model is a simplified representation of a real-world system, but it provides a useful tool for understanding the basic principles of ecology.

### Part 1a: Mathematical Modeling

Mathematical modeling is a powerful tool for understanding complex systems. In this experiment, we will use mathematical modeling to analyze the interactions between different species and the environment during the Ice Age. The model is based on the following assumptions:

- The system is a closed system, meaning that no individuals enter or leave the system.
- The population of each species is represented by a vector  $\mathbf{x}$ , where  $x_i$  is the population of species  $i$ .
- The interactions between species are represented by a matrix  $\mathbf{A}$ , where  $A_{ij}$  is the interaction between species  $i$  and  $j$ .
- The environment is represented by a vector  $\mathbf{e}$ , where  $e_i$  is the value of the  $i$ -th environmental variable.

The model is solved using a numerical method, and the results are plotted against time. The plot shows the population of each species over time, as well as the values of the environmental variables. The results show that the population of each species changes over time, and that the environmental variables also change. The model is a simplified representation of a real-world system, but it provides a useful tool for understanding the basic principles of ecology.

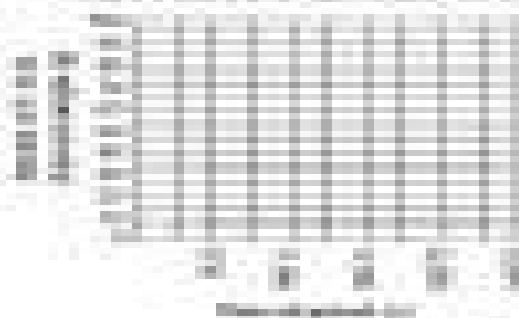

Table 1a

Parameter	Value	Unit
Initial population of species 1	1000	individuals
Initial population of species 2	500	individuals
Initial population of species 3	200	individuals
Initial population of species 4	100	individuals
Initial population of species 5	50	individuals
Initial population of species 6	25	individuals
Initial population of species 7	12.5	individuals
Initial population of species 8	6.25	individuals
Initial population of species 9	3.125	individuals
Initial population of species 10	1.5625	individuals

The model is solved using a numerical method, and the results are plotted against time. The plot shows the population of each species over time, as well as the values of the environmental variables. The results show that the population of each species changes over time, and that the environmental variables also change. The model is a simplified representation of a real-world system, but it provides a useful tool for understanding the basic principles of ecology.
