

Chapter 1 The Science of Biology**Summary****1-1 What Is Science?**

Science is an organized way of using evidence to learn about the natural world. Scientific thinking usually begins with observation, which is the process of gathering information about events or processes in a careful, orderly way. The information gathered from observations is called data. Quantitative data are expressed as numbers, obtained by counting or measuring. Qualitative data are descriptive and involve characteristics that can't usually be counted. Scientists use data to make inferences. An inference is a logical interpretation based on prior knowledge or experience.

After making first observations, a researcher will propose one or more hypotheses. A hypothesis is a proposed scientific explanation for a set of observations. Scientists generate hypotheses using prior knowledge, logical inference, and informed, creative imagination. Scientific hypotheses must be proposed in a way that enables them to be tested. Hypotheses are tested by performing controlled experiments. The conclusions researchers draw from experiments or data must be valid. To be valid, a conclusion must be based on logical interpretation of reliable data.

1-2 How Scientists Work

Conducting a scientific investigation involves a series of steps. The first step is asking a question. The second step involves forming a hypothesis. The third step in conducting a scientific investigation is setting up a controlled experiment. A hypothesis should be tested by an experiment in which only one variable is changed at a time. All other variables should be kept unchanged. This type of experiment is called a controlled experiment. The variable that is deliberately changed is called the manipulated variable. The variable that is observed and that changes in response

to the manipulated variable is called the responding variable.

The fourth step in conducting a scientific investigation is recording and analyzing results. The fifth step is drawing a conclusion. A key assumption in science is that experimental results can be reproduced.

As evidence builds up, a particular hypothesis may become so well supported that scientists consider it a theory. In science, a theory is a well-tested explanation that unifies a broad range of observations.

1-3 Studying Life

Although living things vary greatly, all living things share eight characteristics:

1. Living things are made up of units called cells. Cells are the smallest units of an organism that can be considered alive.
2. Living things reproduce. In sexual reproduction, cells from two different parents unite to produce the first cell of the new organism. In asexual reproduction, a single cell divides in half to form two new organisms.
3. Living things are based on a universal genetic code. The directions for inheritance are carried by a molecule called DNA.
4. Living things grow and develop. Multicellular organisms typically go through a process called development. As cells divide, they change in shape and structure in a process called differentiation.
5. Living things obtain and use materials and energy. The combination of chemical reactions through which an organism builds up or breaks down materials as it carries out its life processes is called metabolism.

Biology Kenneth Raymond Miller, Prentice Hall (School Division), 1999-02 **Introduction to Molecular Biology, Genomics and Proteomics for Biomedical Engineers** Robert B. Northrop, Anne N. Connor, 2008-10-28 Illustrates the Complex Biochemical Relations that Permit Life to Exist It can be argued that the dawn of the 21st century has emerged as the age focused on molecular biology which includes all the regulatory mechanisms that make cellular biochemical reaction pathways stable and life possible For biomedical engineers this concept is essential to **International Environmental Law, Policy, and Ethics** Alexander Gillespie, 2014-08-21 This second edition of International Environmental Law Policy and

Ethics revises and expands this groundbreaking study into the question of why the environment is protected in the international arena. This question is rarely asked because it is assumed that each member of the international community wants to achieve the same ends. However, in his innovative study of international environmental ethics, Alexander Gillespie explodes this myth. He shows how nations like individuals create environmental laws and policies which are continually inviting failure as such laws can often be riddled with inconsistencies and be ultimately contradictory in purpose. Specifically, he seeks a nexus between the reasons why nations protect the environment, how these reasons are reflected in law and policy, and what complications arise from these choices. This book takes account of the numerous developments in international environmental law and policy that have taken place since the publication of the first edition, most notably at the 2002 World Summit on Sustainable Development and the 2012 Rio 20 United Nations Conference on Sustainable Development. Furthermore, it addresses recent debates on the economic value of nature and the problems of the illegal trade in species and toxic waste. The cultural context has also been considerably advanced in the areas of both intangible and tangible heritage, with increasing attention being given to conservation, wildlife management, and the notion of protected areas. The book investigates the ways in which progress has been made regarding humane trapping and killing of animals, and how, in contrast, the Great Apes initiative and similar work with whales have failed. Finally, the book addresses the fact that while the notion of ecosystem management has been embraced by a number of environmental regimes, it has thus far failed as an international philosophy.

English Mechanic and Mirror of Science and Art, 1904 *English Mechanic and World of Science*, 1905 *Dynamic Systems: Biology, Modeling, and Simulation* Joseph DiStefano III, 2015-01-10

Dynamic Systems: Biology, Modeling, and Simulation consolidates and unifies classical and contemporary multiscale methodologies for mathematical modeling and computer simulation of dynamic biological systems from molecular, cellular, organ, system, on up to population levels. The book's pedagogy is developed as a well-annotated systematic tutorial with clearly spelled out and unified nomenclature derived from the author's own modeling efforts, publications, and teaching over half a century. Ambiguities in some concepts and tools are clarified, and others are rendered more accessible and practical. The latter include novel qualitative theory and methodologies for recognizing dynamical signatures in data using structural, multicompartmental, and network models, and graph theory, and analyzing structural and measurement data models for quantification feasibility. The level is basic to intermediate, with much emphasis on biomodeling from real biodata for use in real applications. Introductory coverage of core mathematical concepts such as linear and nonlinear differential and difference equations, Laplace transforms, linear algebra, probability, statistics, and stochastic topics. The pertinent biology, biochemistry, biophysics, or pharmacology for modeling are provided to support understanding the amalgam of math modeling with life sciences. Strong emphasis on quantifying as well as building and analyzing biomodels includes methodology and computational tools for parameter identifiability and sensitivity analysis, parameter estimation from real data, model distinguishability, and
