

Sunscreens play a crucial role in protecting skin from the harmful effects of ultraviolet (UV) radiation. These products contain organic and inorganic compounds that either absorb, reflect, or scatter sunlight, including UVA and UVB rays, both of which are linked to skin cancer and premature skin aging. Organic ingredients, like oxybenzone and avobenzone, absorb UV radiation, converting it into a small amount of heat. Inorganic components, such as zinc oxide and titanium dioxide, act as physical barriers, reflecting or scattering UV light.

Recent advancements in sunscreen technology have focused on improving the spectral breadth of protection, water resistance, and cosmetic acceptability. Nanoparticle technology, for example, has allowed for the formulation of more aesthetically pleasing physical sunscreens by reducing the whitening effect of inorganic particles. Furthermore, the development of photostable UV filters has improved the efficacy and durability of sunscreens under sun exposure.

Despite their benefits, the environmental impact of sunscreen chemicals has raised concerns. Ingredients like oxybenzone have been found to contribute to coral bleaching and aquatic toxicity. As a response, researchers are developing more eco-friendly formulations that are as effective in sun protection but have reduced environmental footprints. This ongoing research underscores the importance of balancing human health benefits with environmental sustainability in sunscreen development.

This is the environment in which particles and organisms of a range of sizes live from tiny plankton to megafauna. This generates faunal connectivity at scales of meters to thousands of km within the Great Barrier Reef and with the adjoining ocean. Pollution from land use is increasing and remedial measures are described both on land and on coral cays. The impact of climate change is quantified in case studies about mangroves and corals.
