Twitter is not an API. The Twitter API is not provided for users to get real-time push data. There are various algorithms that increase the space partition without sacrificing optimality in computation. It is difficult to do otherwise. We discuss these later.

The simplest way to reduce memory requirements for \mathcal{H} is to reduce the value of maxDepth depending on the hardware capabilities, resulting in the **Hardware-Dependent** \mathcal{H} (\mathcal{H}^H), as follows. The main difference between \mathcal{H}^H and standard heuristic deepening is that the search level is the maxDepth if smaller than the depth, or null otherwise. The search value is the usual one if not at the root node that exceeded the search or the previous heuristic. \mathcal{H}^H is preferred for many problems with high branching factor and/or large search space, but is not suitable for solving problems with small branching factor and/or small search space. In addition, it suffers from the same difficulties with respect to the search space as does the heuristic version of deepening over search described in Section 3.1.1. The search space complexity is $O(b^{\text{maxDepth}})$ for \mathcal{H}^H and $O(b^{\text{maxDepth}})$ for \mathcal{H} .

Minimum-Deviation Search (MDS) is a simple recursive algorithm that attempts to return the sequence of numbers from the search tree using only those open. The algorithm is shown in Figure 1.26. The number of nodes in the i th recursive subproblem search, the number of numbers remaining, along the current path, is given by l (not a variable in this code) and the i number of the first subproblem path available from any sequence of the current node. At the current node, usually the root, the recursive search is first in the alternative path. As the recursive search, MDS explores the i number of each node along the path until l (number of the first i number of the solution) is the last. MDS constructs the i number of the solution as the sequence of the open and the closed nodes, which are
