

thinking: If the rate of release of  $\text{CO}_2$  from the biota was growing at an identical rate to the  $\text{CO}_2$  release from fossil fuels, we would find it hard to detect; and if the biotic release was matched by some unknown  $\text{CO}_2$  sink, the releases could indeed be large. So far we cannot unequivocally support either of these scenarios.

In summary, the recent estimates of an atmospheric  $\text{CO}_2$  concentration of about 265 ppm around 1850 lead to a predicted warming greater than that yet observed today if we use the upper range of climate model results, and point to a net  $\text{CO}_2$  source from the terrestrial biosphere contributing about 25 ppm to the atmospheric levels. This flux from the biota most likely occurred in the late nineteenth century and early decades of this century. The net release from the biosphere today could be about 2 Gt of C per year, although lesser or negative fluxes would not be inconsistent with oceanic and atmospheric models. Finally, we must keep in mind, as Revelle's analysis (Section 3.5) of methane hydrates in continental slope sediments suggests, that climate change may bring about surprising changes in fluxes of carbon.

### 3.2 CARBON DIOXIDE AND THE OCEANS

*Peter G. Brewer*

The effect of solution of the gas by the sea water was next considered, because the sea acts as a giant regulator of carbon dioxide and holds some sixty times as much as the atmosphere. The rate at which the sea water could correct an excess of atmospheric carbon dioxide depends mainly upon the fresh volume of water exposed to the air each year, because equilibrium with the atmospheric gases is only established to a depth of about 200 m during such a period. The vertical circulation of the oceans is not well understood, but several factors point to an equilibrium time, in which the whole sea volume is exposed to the atmosphere of between two and five thousand years.

--Callendar (1938)

#### 3.2.1 Introduction

The quotation above is still, after more than 40 years of progress, as succinct a statement of the problem as one could desire. The rising atmospheric  $\text{CO}_2$  level has been carefully measured since 1958. Calculations made on the amount of fossil fuel  $\text{CO}_2$  released during this time, based on good records of oil, coal, and gas combustion, show that the observed increase in atmospheric  $\text{CO}_2$  is a little more than half the amount of fossil fuel  $\text{CO}_2$  input.

Boucot,2013-10-22 This book is the culmination of many years of research by a scientist renowned for his work in this field It contains a compilation of the data dealing with the known stratigraphic ranges of varied behaviors chiefly animal with a few plant and fungal and coevolved relations A significant part of the data consists of frozen behavior i e those in which an organism has been preserved while actually doing something as contrasted with the interpretations of behavior of an organism deduced from functional morphology important as the latter may be The conclusions drawn from this compilation suggest that both behaviors and coevolved relations appear infrequently following which there is relative fixity of the relation i e two rates of evolution very rapid and essentially zero This conclusion complies well with the author s prior conclusion that community evolution followed the same rate pattern In fact communities are regarded here as in large part expressions of both behavior and coevolved relations rather than as random aggregates controlled almost wholly by varied unrelated physical parameters tracked by organisms i e the concept that communities have no biologic reality being merely statistical abstractions The book
