Figure 3.5.6 The recursive best-first search algorithm.

Figure 3.5.6 shows one of many. The algorithm in Figure 3.5.6 is an elegant but naive implementation of RBFS. There are numerous algorithms that implement the same problem without requiring explicitly an implementation of a minimax or maximax node. We discuss these next.

### 3.5.2 Iterative Deepening Search

The simplest way to reduce memory requirements for BF is to allow the idea of iterative deepening in the heuristic search context, resulting in the **Iterative Deepening ID-DFS** algorithm. The main difference between ID-DFS and standard heuristic deepening is that the search explores the frontier in breadth-first order, as with breadth-first search, but the search is limited to a fixed *f*-cost such that exceeded the search is the previous iteration. ID-DFS is similar to naive breadth-first search, but it does not require the additional overhead associated with keeping a frontier of nodes. Unfortunately, it suffers from the same difficulties with respect to time as does the breadth-first search algorithm described in Figure 3.5.1. The worst-case time complexity for iterative deepening algorithms, including ID-DFS and ID-BFS, is  $O(b^{f_{\max}})$ .

**Iterative Deepening Search.** IDDFS is a simple heuristic algorithm that attempts to solve the problem of searching for the search tree using only those given. The algorithm is shown in Figure 3.5.7. Its operation is similar to that of a recursive depth-first search. The algorithm maintains a frontier, stores the current node, and uses the current variable to keep track of the *f*-value of the best alternative path available from the previous *f*-cost node. If the current node exceeds the limit, the search returns back to the alternative path. As the search proceeds, IDDFS explores the frontier of each node along the path until reaching a leaf. The best *f*-value of an iteration is the new IDDFS maximum. The *f*-value of the search is the highest value and the heuristic search returns the node.
