Alkali Metals:
One valence electron
Very reactive because they are ready to lose an electron to form cations
Weakly in ionic bonds due to reactivity
Bonds with halogens, and other non-metals
Have a vigorous reaction when bonding with halogens, oxygen and the compound of water

Alkaline Earth Metals:
Two valence electrons
Inert but not as reactive as halogens and alkali metals because it needs to lose 2 electrons to have a full valence shell
Bonds with halogens, and other non-metals

Transition Metals/ Metals: Transition metals are metals that vary in valence electrons and can have multiple ion charges. They have similar qualities as alkali metals and alkaline earth metals; they can form metallic and ionic bonds. Metals with multiple ion charges are called multivalent metals. For example, copper has an ion charge of +1 and +2 so it is a multivalent metal. Therefore, the ion charge must be specified when written in word form for ionic bonds with multivalent metals. Metals can also bond with polyatomic ions.

Metalloids: Contain metal and non-metal properties. They react with metals and non-metals to form covalent and ionic bonds but are less reactive than non-metals, depending on the electronegativity of the atoms.

Non-metals: They can not conduct electricity because they can not give off electrons, so current will not be able to go through.
Non-metals bond with metals in an ionic bond and other non-metals in a molecular bond. They can also bond with the polyatomic ion ammonium due to its +1 charge.

Noble Gases: Non-metals in a previous form that have a full valence shell. This makes it not reactive, so it can not bond with other non-metals and metals. This is why noble gases are never in compounds and chemical reactions.
