

How has the earth's climate changed in the past few decades?

In recent year, we are facing a series of pressing environmental issues on a global level, including climate change, biodiversity degradation, freshwater degradation, ozone degradation, etc. Especially, the phrase "climate change" has been of great interest. It is not only adversely impacting human life in the present, but also threatening future habitats. Although, both natural and human influences are also impacting climate change. But human influence has been the major cause of climate change in the past few decades. Over time, climate change has changed a lot including precipitation, temperature, and wind patterns.

Weather is the daily state of the atmosphere such as temperature, and humidity. Humans can directly recognize weather changes. On the contrary, humans cannot directly recognize climate change. Climate is a scientific concept. It is related to statistics, as the average value of weather events usually appears for a long time about 30 years. Therefore, climate change does not show a change in the weather conditions that we experience every day or every year. Instead, it is the difference in long-term weather conditions in a particular area.

Throughout the history of the earth, the climate has changed naturally and temperatures have fluctuated greatly, causing climatic phenomena such as the "ice age". However, the temperature of the earth has risen higher and faster than any time we know of in the past. Nowadays, across the earth, temperatures are getting hotter sometimes referred to as warming earth and weather forms are changing. "The global average temperatures compared to pre-industrial levels at the end of the century are predicted to be at the highest levels from 1.5 °C to 2 °C" according to WMO Secretary-General Professor Petteri Taalas. Climate changes will have enormous effects on humans including human activity such as agriculture and all species on the planet. The results of a new study published in the journal *The Cryosphere* show that "In the 1990s, the world lost about 800 billion tons of ice per year. Today, that number increases to about 1,200 billion tons per year. And in total, the planet lost 28 trillion tons of ice between 1994 and 2017"(2021). So that ice is slowly disappearing around the world and largely due to climate change.

As global temperatures rising, the ice in glaciers and the arctic and Antarctica will melt, spawning huge amounts of water flowing into the sea. At that time, sea levels will rise, flooding coastal lowlands and deep inland around the world. In addition, the increase in temperature leads to the expansion of the water, which also causes sea levels to increase higher. "For most of the time in the 20th century, the global
