Robards, 2011-10-13 Times of dramatic progress in brain research have often been correlated with the development of new and powerful techniques that have changed the kinds of questions one can ask An historical example may illustrate the point More than 50 years ago Nissl studies Ferraro 1928 showed that extensive forebrain lesions resulted in chromatolysis and cell loss in the substantia nigra thus it was suggested that the substantia

nigra gave rise to projections into the basal forebrain In the late 1950s another clue emerged this time linking observations from the field of neuropathology with a discovery in experimental neuropharmacology Carlsson 1959a b Ehringer and Hornykiewicz 1960 It had long been recognized that patients with Parkinson's disease suffered neuronal loss in the substantia nigra and that their symptoms were somehow related to striatal dysfunction Thus when fluorescent catecholamine assays were developed and combined with pharmacological and neuropathological studies of Parkinson's disease the dopaminergic nature of the illness was shown A bit later Falck and Hillarp Falck et al 1962 developed a fluorescent histochemical method to visualize monoamine containing cells in the brain this technique was soon applied to show that the rich dopaminergic terminal field in the striatum derived from neurons in the substantia nigra Anden et al 1964 In the following decade refinements in the histofluorescent method and the development of sensitive silver impregnation methods permitted a detailed light microscopic exploration of the dopaminergic nigrostriatal system Transsynaptic Tracing by in Situ Complementation of a Deletion Mutant Neurotropic Virus Ian R. Wickersham, 2006 We have developed two new tools for tracing neural connections The first is a means of identifying cells that project to a region of interest within the brain illuminating these cells with intense fluorescence and allowing their finest morphological details to be seen This permits either highly detailed reconstruction of the cells anatomy or their targeting in live tissue on the basis of their morphology for physiological study The second tool is a means of identifying on a large scale neurons which are directly presynaptic to either a targeted cell type or indeed a single neuron Because this technique also results in intensely fluorescent cellular details this too could be used either for detailed anatomical studies or for physiological ones This should allow a significantly more precise understanding of the organization of nervous systems than has previously been possible
