

Keystone Species

Saguaro Cactus

What is a keystone species?

A keystone species is a species that has a disproportionately large effect on its environment relative to its abundance. The concept was developed by ecologist Robert Paine in 1969, based on his work with intertidal invertebrates. The term "keystone" is derived from the keystone of an arch, which is the central, topmost stone that holds the entire structure together.

Keystone species play a critical role in maintaining the structure of an ecosystem. They can be found in a wide variety of habitats, from coral reefs to grasslands. Some keystone species are predators, while others are engineers or mutualists. The loss of a keystone species can lead to a dramatic change in the ecosystem, often resulting in a loss of biodiversity.

Why is the Saguaro a keystone species?

The Saguaro cactus is a keystone species in the Sonoran Desert. It provides food and shelter for a wide variety of animals, including birds, mammals, and reptiles. The cactus also plays a role in the desert's water cycle, storing water in its thick stems and releasing it into the soil. Without the Saguaro, the desert ecosystem would be fundamentally altered.
