The reinforcement lead is applied in the stability analysis either as a single stabiliting element or a series of reinforcing elements to achieve the desired factor of safety. The length of the bolt or cable is dependent on the bond strength (adhesion to the nock) and the discontinuity spacing that forms the deepest part of the black. Tendon lengths can range from 2 to 30 m (6 to 100 ff); however, in the transportation industry, the tendon length rarely exceeds 10 m (30 ff). The detailed requirements for site investigation and analysis of rock cuts are provided in FHWA HI-99-007 Rock Slopes Reference Manual (Munfakh, Wyllie, and Mah 1998).

Rock anchors are usually installed in a grid pattern, where such anchor is the same length and set at a predetermined distance from the surrounding bolts. Following a set pattern can improve the structural stability of an entire rock face, especially fire weathered or highly fractured rock. On competent rock masses with large block sizes, engineers typically identify "key blocks" (i.e., blocks of rock that control support for surrounding blocks), then design a bolting pattern around them that makes it more difficult for the surrounding blocks to move. Designing a key block pattern requires engineers to map the three-dimensional fracture orientations, but can decrease the number of took bolts required to stabilize a slope:

In both tensioned and untensioned anchors, the bearing plate and her nut are used to distribute the load of the anchor to the rock face; a beveled washer is used to apply the load evenly when the bolt is angled in relation to the rock face. In rock masses with few discontinuities, the plate can be removed and the tendon (bur as cubic) cut to allow for the installation of a grout cover or plug. This method is highly contingent on the quality of rock and stability of the rock mass.
