

Figure 3 — Cruciform angle sections

5.3 Primary bracing members

5.3.1 General

Typical primary bracing patterns are shown in Figure 4.

Secondary bracings can be used to subdivide the primary bracing or main leg members as shown, for example, in Figures 4 and 5.

NOTE: A maximum effectiveness/slenderness ratio of 180 for primary bracing members is good practice.

5.3.2 Single lattice

A single lattice is commonly used where the loads are light and the length relatively short, as for instance near the top of towers or in light guyed masts [see Figure 4(a) and g)]. The slenderness ratio, λ , should be taken as:

$$\begin{aligned}\lambda &= L_d/r_{yy} && \text{for angles;} \\ \lambda &= L_d/r_{xx} && \text{for tubes or solid rounds.}\end{aligned}$$

5.3.3 Cross bracing systems

5.3.3.1 Cross bracing without secondary members

Provided that:

- the load is equally split into tension and compression; and
- both members are continuous [see Figure 4(b)]; and
- the members are adequately connected where they cross, then the centre of the connection may be considered as a point of restraint both transverse to and in the plane of the bracing and the critical system length becomes length L_{d2} on the minimum axis. The slenderness ratio, λ , should be taken as:

$$\begin{aligned}\lambda &= L_{d2}/r_{yy} && \text{for angles;} \\ \lambda &= L_{d2}/r_{xx} && \text{for tubes.}\end{aligned}$$

NOTE: Where either member is not continuous, the centre of the connection may only be considered as a restraint in the transverse direction if the detailing of the centre connection is such that the effective lateral stiffness of both members is maintained through the connection and the longitudinal axial stiffness is similar in both members.

When the load is not equally split into tension and compression and provided both members are continuous, the compression members should be checked for the worst compressive load. In addition, it should be checked that the sum of the load carrying capacities of both members in compression is at least equal to the algebraic sum of the loads in the two members. For the calculations of these load carrying capacities, the system length is the whole length L_d and the radius of gyration is that about the rectangular axis parallel to the plane of the bracing. The value of the slenderness ratio, λ , should be taken as one of the following:

$$\begin{aligned}\lambda &= L_d/r_{xx} \quad \text{or} \quad \lambda = L_d/r_{yy} && \text{for angles;} \\ \lambda &= L_d/r_{xx} && \text{for tubes or solid rounds.}\end{aligned}$$

5.3.3.2 Cross bracing with secondary members

Where secondary members are inserted [see Figure 4(h) and Figure 5(a) and b)], they reduce the system length of the bracing member on the minimum axis to L_{d1} . The slenderness ratio, λ , should be taken as:

$$\begin{aligned}\lambda &= L_{d1}/r_{yy} && \text{for angles;} \\ \lambda &= L_{d1}/r_{xx} && \text{for tubes or solid rounds} \\ &&& \text{(normally not critical).}\end{aligned}$$

Buckling should also be checked over the system length L_{d2} on the rectangular axis for buckling transverse to the bracing and, when the load is not equally split into tension and compression, over the system length L_d for the algebraic sum of the loads (see 5.3.3.1).
