1. The first step is to identify the problem or question that needs to be answered. This involves understanding the context and the specific requirements of the task.

1. **Identify the problem.** The first step is to identify the problem. This involves understanding the symptoms and the context in which they are occurring. For example, if a patient is experiencing chest pain, the problem could be a heart attack, a lung infection, or a musculoskeletal issue.

2. **Collect data.** The next step is to collect data. This involves gathering information about the patient's history, current symptoms, and any relevant test results. This data is used to narrow down the possible causes of the problem.

3. **Analyze the data.** The third step is to analyze the data. This involves comparing the collected information against known medical knowledge and patterns. This step helps to identify the most likely cause of the problem.

4. **Formulate a hypothesis.** The fourth step is to formulate a hypothesis. This is a tentative explanation for the problem, based on the analysis of the data. The hypothesis is then tested through further investigation.

5. **Implement a solution.** The fifth step is to implement a solution. This involves developing a plan of action to address the problem. This plan may include medical treatment, lifestyle changes, or other interventions.

6. **Evaluate the outcome.** The final step is to evaluate the outcome. This involves monitoring the patient's response to the intervention and determining whether the problem has been resolved. If not, the process may need to be repeated.
