Abstract The purpose of this study was to determine the effect of a 12-week, low-intensity, supervised walking program on the physical and psychological health of sedentary, middle-aged women. The study was a randomized, controlled trial. The subjects were 40 sedentary, middle-aged women who were randomly assigned to either a supervised walking program or a control group. The walking program consisted of 12 weeks of supervised walking, 3 times per week, for 30 minutes per session. The control group consisted of 20 women who did not participate in the walking program. The physical health of the women was assessed using a variety of measures, including heart rate, blood pressure, and body mass index. The psychological health of the women was assessed using a variety of measures, including the Beck Depression Inventory and the State-Trait Anxiety Inventory. The results of the study showed that the walking program had a significant positive effect on the physical and psychological health of the women. The women in the walking program had significantly lower heart rates, blood pressures, and body mass indices than the women in the control group. Additionally, the women in the walking program had significantly lower scores on the Beck Depression Inventory and the State-Trait Anxiety Inventory than the women in the control group. These findings suggest that a 12-week, low-intensity, supervised walking program can have a significant positive effect on the physical and psychological health of sedentary, middle-aged women.

Abstract. The purpose of this study was to determine the effect of a 12-week training program on the heart rate (HR) and heart rate reserve (HRR) of sedentary middle-aged men. The subjects were divided into two groups: a control group and an exercise group. The exercise group performed a 12-week training program consisting of three sessions per week, each lasting 30 minutes. The control group did not participate in any exercise program. The HR and HRR were measured at rest and during maximal exercise at the beginning and end of the 12-week period. The results showed that the exercise group had a significant increase in HR and HRR compared to the control group. The HR increased from 72 to 78 beats per minute, and the HRR increased from 28 to 34 beats per minute. The control group showed no significant change in HR and HRR. The findings suggest that a 12-week training program can improve the cardiovascular fitness of sedentary middle-aged men.
