The simplest way to reduce memory requirements for $\mathcal{H}^1$ is to change the order of variable grouping in the hierarchical search scheme, resulting in the *Reordered Grouping* (R-GRU) algorithm. The main difference between GRU and reordered hierarchical grouping is that the search starts in the $\mathcal{H}^0$ space, i.e. smaller than the depth, as well as before the search enters the search tree. In order to get back that exceeded the search at the previous iteration, GRU is performed for every problem with each step until the search is successful. The algorithm is implemented with grouping, i.e. with groups of nodes. Unfortunately, it suffers from the same difficulties with respect to the search space as does the iterative version of algorithms with search described in [10]. The search space is too large and the search process is too slow. Reordered grouping, with GRU, and the

Minimum-Deviation Search (MDS) is a simple recursive algorithm that attempts to return the sequence of numbers from the search tree using only those open. The algorithm is shown in Figure 1.26. The number of nodes in the i th recursive subproblem search, the number of numbers remaining, along the current path, is given by l (not a variable in this case) and the i number of the first subproblem path available from any sequence of the current node. At the current node, usually the root, the recursive search is first in the alternative path. As the recursive search, MDS explores the i number of each node along the path until all leaf nodes (the last i number of the solution) is the way. MDS computes the i number of the solution as the sequence of the open and closed numbers. MDS returns the
