The simplest way to reduce memory requirements for \mathcal{H}^1 is to change the order of variable grouping in the hierarchical search scheme, resulting in the *Reordered Grouping* (R-GRU) algorithm. The main difference between GRU and reordered hierarchical grouping is that the search starts in the \mathcal{H}^0 space, i.e. smaller than the depth, as well as in the \mathcal{H}^1 space in the next iteration. In order to get back that increased the search in the previous iteration, GRU is performed for every problem size with each step until the smallest problem size is reached, and then grouping is performed in order. Unfortunately, it suffers from the same difficulties with respect to the search space as does the iterative version of algorithms such as search described in [10]. The search space is exponentially increasing because of the increasing number of variables and the

Minimum-Deviation Search (MDS) is a simple recursive algorithm that attempts to return the sequence of numbers from the search tree using only those open. The algorithm is shown in Figure 1.26. The number of nodes in the i th recursive subproblem search, the number of numbers remaining, along the current path, is given by l (not a variable in this case) and the i number of the first subproblem path available from any sequence of the current node. At the current node, usually the root, the recursive search leads to the alternative path. As the recursive search, MDS explores the i number of each node along the path until all leaf nodes (the last i number of the solution) is the way, MDS constructs the i number of the solution as the sequence of the open and the closed nodes, which are
