Determination of Heating and Cooling Loads for a Residential Dwelling Edward P. Lyons, 1976 **Residential Heating and Cooling Loads and Costs for the South**, 1982 This report examines typical residential heating and cooling loads for 24 southern cities and six other US cities A 1536 square foot house is examined with concrete slab floor frame construction ventilated attic and glazing area equivalent to 12% of the floor area Five basic variations of this house were analyzed two insulation levels with two compass orientations each and a sun tempered case The building load calculations were based on a non rigorous methodology typically used within the building community today The estimated heating and cooling loads and the impact of insulation orientation and sun tempering are illustrated with regional maps Typical fuel costs and heating systems are also examined and shown to have a major role in determining whether the building design emphasis should be on heating or cooling Evaluation of Heating Loads in Old Residential Structures United States. Department of

Housing and Urban Development. Office of Policy Development and Research, Hittman Associates, 1974 **A Bottom-up Engineering Estimate of the Aggregate Heating Andcooling Loads of the Entire U.S. Building Stock**, 2000 A recently completed project for the U S Department of Energy s DOE Office of Building Equipment combined DOE 2 results for a large set of prototypical commercial and residential buildings with data from the Energy Information Administration EIA residential and commercial energy consumption surveys RECS CBECS to estimate the total heating and cooling loads in U S buildings attributable to different shell components such as windows roofs walls etc internal processes and space conditioning systems This information is useful for estimating the national conservation potentials for DOE s research and market transformation activities in building energy efficiency The prototypical building descriptions and DOE 2 input files were developed from 1986 to 1992 to provide benchmark hourly building loads for the Gas Research Institute GRI and include 112 single family 66 multi family and 481 commercial building prototypes The DOE study consisted of two distinct tasks 1 perform DOE 2 simulations for the prototypical buildings and develop methods to extract the heating and cooling loads attributable to the different building components and 2 estimate the number of buildings or floor area represented by each prototypical building based on EIA survey information These building stock data were then multiplied by the simulated component loads to derive aggregated totals by region vintage and building type The heating and cooling energy consumption of the national building stock estimated by this bottom up engineering approach was found to agree reasonably well with estimates from other sources although significant differences were found for certain end uses The main added value from this study however is the insight it provides about the contributing factors behind this energy consumption and

Heating and Cooling Load Calculations P. G. Down, 1969 Energy and Cost Analysis of Residential Heating Systems Dennis L. O'Neal, 1978 Calculating Building Heating and Cooling Loads Using the Frequency Response of Multilayered Slabs Douglas Hittle, CONSTRUCTION ENGINEERING RESEARCH LAB (ARMY) CHAMPAIGN IL., 1981 This thesis describes the development of a method for calculating room heating and cooling loads using frequency response methods to calculate heat flow through multi layered room walls and roofs Existing methods for calculating room loads are discussed and the need to consider the effects of thermal mass are emphasized A detailed derivation of the solution of the transient one dimensional heat conduction equation for multi layered slabs which leads to the calculation of response factors and conduction transfer functions is presented Next the special case of a fixed temperature on one side of a multi layered slab and a sinusoidal temperature variation on the other side is examined and the simplifications which result are described This frequency response method for calculating heat flow can be applied to buildings if the outdoor climate can be represented by a reasonably small number of sinusoidal components To determine the extent of sinusoidal variation in climate time series analysis techniques were applied to hourly measured weather data from four climatically different sites in order to separate the deterministic periodic behavior in the data from its stochastic behavior A combined deterministic plus stochastic model was found to be adequate for the climate variables studied This model included as its deterministic component sinusoids with frequencies corresponding to the annual cycle the diurnal cycle and the first harmonic of the diurnal cycle The use of this method as part of a simplified room load calculating procedure was compared to results from a more detailed approach and again very good agreement was found An Analysis of Representative Heating Load Lines for Residential HSPF Ratings , 2015 This report describes an analysis to investigate representative heating loads for single family detached homes using current EnergyPlus simulations DOE 2014a Hourly delivered load results are used to determine binned load lines using US Department of Energy DOE residential prototype building models DOE 2014b developed by Pacific Northwest National Laboratory PNNL The selected residential single family prototype buildings are based on the 2006 International Energy Conservation Code IECC 2006 in the DOE climate regions The resulting load lines are compared with the American National

Standards Institute ANSI Air Conditioning Heating and Refrigeration Institute AHRI Standard 210 240 AHRI 2008 minimum and maximum design heating requirement DHR load lines of the heating seasonal performance factor HSPF ratings procedure for each region The results indicate that a heating load line closer to the maximum DHR load line and with a lower zero load ambient temperature is more representative of heating loads predicted for EnergyPlus prototype residential buildings than the minimum DHR load line presently used to determine HSPF ratings An alternative heating load line equation was developed and compared to binned load lines obtained from the EnergyPlus simulation results The effect on HSPF of the alternative heating load line was evaluated for single speed and two capacity heat pumps and an average HSPF reduction of 16% was found The alternative heating load line relationship is tied to the rated cooling capacity of the heat pump based on EnergyPlus autosizing which is more representative of the house load characteristics than the rated heating capacity The alternative heating load line equation was found to be independent of climate for the six DOE climate regions investigated provided an adjustable zero load ambient temperature is used For Region IV the default DOE climate region used for HSPF ratings the higher load line results in an 28% increase in delivered heating load and an 52% increase in the estimated heating operating cost over that given in the AHRI directory AHRI 2014
