return a node out of order. For this reason, it is not possible for nodes deeper under paths than an optimal solution to be expanded. The given problem without searching globally is equivalent to a depth-first search problem. We discuss this next.

### 3.5.2. Heuristic-Bounded Best-First Search

The simplest way to allow domain-independent heuristics for  $A^*$  is to allow the value of heuristic functions to be negative, which means searching in the *Reverse-Ordering* of  $A^*$  (3.5.1.2) problem. The main difference between RBFS and ordered best-first searching is that the latter expands nodes in order of their *f*-costs, whereas the former expands the nodes with the lowest *f*-costs. In order to use nodes that exceeded the cutoff as the previous heuristic, RBFS is applied to the given problem with only one goal and expands the solutions according to their *f*-costs. This is done by using the heuristic function as a cost function. The algorithm expands nodes in order of their *f*-costs, which is the same as expanding nodes according to their *f*-costs. The algorithm expands nodes in order of their *f*-costs, which is the same as expanding nodes according to their *f*-costs.

**Heuristic-Bounded Search.** RBFS is a search algorithm dependent that attempts to return the solution of a search tree for a given problem with finite goals. The algorithm is shown in Figure 3.5.10. An heuristic is applied in order of increasing *f*-costs. The value of the heuristic is calculated, and the nodes with the lowest *f*-costs are expanded first. If the search ends without the goal, the heuristic is applied to the remaining nodes. If the heuristic is applied to the remaining nodes, the algorithm returns the solution of the search tree. The algorithm expands nodes in order of their *f*-costs, which is the same as expanding nodes according to their *f*-costs.
