Figure 3.5.6 The recursive best-first search algorithm.

Figure 3.5.6 shows one of many ways that the recursive RBFS algorithm for node *node* keeps track of *f*-costs. There are numerous algorithms that implement the same problem without recording *f*-costs, or recording *f*-costs in a different manner. We discuss these next.

3.5.2 Memory-Bounded Heuristic Search

The simplest way to reduce memory requirements for RBFS is to allow the idea of heuristic weighting in the heuristic search process, resulting in the **Heuristic Weighting RBFS** algorithm. The main difference between RBFS and heuristic heuristic weighting is that the cost of a node is $f(\text{node}) = g(\text{node}) + h(\text{node})$, as usual, but the *weight* of the cost of the node is the *weight* of the *g*-cost of the previous function. RBFS is applied to the same problem with only one cost, and records the minimum weighted *f*-cost instead of keeping a table of *f*-costs. Unfortunately, it differs from the naive definition with one subtle case in that the heuristic values of children can be *negative* (Figure 3.5.7). The next section considers several other memory-bounded algorithms, called MBBS and MBBS_{max}.

Heuristic Weighting Search (HWRBS) is a simple recursive algorithm that attempts to solve the problem of heuristic search search, but using only *one* cost. The algorithm is shown in Figure 3.5.8. Its behavior is similar to that of a recursive depth-first search, but rather than maintaining a table of *f*-costs, it uses the current variable *weight* to keep track of the *f*-cost of the best alternative path available from any position of the search tree. If the current node exceeds this limit, the recursive search back to the alternative path. In the recursive version, HWRBS updates the *weight* of each node along the path with *weightingFactor* (the *weight* of its children). In this way, HWRBS maintains the *f*-cost of the search in the *weight* value, and can therefore decide whether or not

Rescuing Econometrics Duo Qin,2023-12-01 Haavelmo s 1944 monograph The Probability Approach in Econometrics is widely acclaimed as the manifesto of econometrics This book challenges Haavelmo s probability approach shows how its use is delivering defective and inefficient results and argues for a paradigm shift in econometrics towards a full embrace of machine learning with its attendant benefits Machine learning has only come into existence over recent decades whereas the universally accepted and current form of econometrics has developed over the past century A comparison between the two is however striking The practical achievements of machine learning significantly outshine those of econometrics confirming the presence of widespread inefficiencies in current econometric research The relative efficiency of machine learning is based on its theoretical foundation and particularly on the notion of Probably Approximately Correct PAC learning Careful examination reveals that PAC learning theory delivers the goals of applied economic modelling research far better than Haavelmo s probability approach Econometrics should therefore renounce its outdated foundation and rebuild itself upon PAC learning theory so as to unleash its pent up research potential The book is catered for applied economists econometricians economists specialising in the history and methodology of economics advanced students philosophers of social sciences **Guide to**
