

phosphate buffer

Information from cshprotocols.org:

Gomori buffers, the most commonly used phosphate buffers, consist of a mixture of monobasic dihydrogen phosphate and dibasic monohydrogen phosphate. By varying the amount of each salt, a range of buffers can be prepared that buffer well between pH 5.8 and pH 8.0 (please see the tables below). Phosphates have a very high buffering capacity and are highly soluble in water. However, they have a number of potential disadvantages:

- * Phosphates inhibit many enzymatic reactions and procedures that are the foundation of molecular cloning, including cleavage of DNA by many restriction enzymes, ligation of DNA, and bacterial transformation.
- * Because phosphates precipitate in ethanol, it is not possible to precipitate DNA and RNA from buffers that contain significant quantities of phosphate ions.
- * Phosphates sequester divalent cations such as Ca^{2+} and Mg^{2+} .

Dilute the combined 1 M stock solutions to 1 liter with distilled H_2O . pH is calculated according to the Henderson-Hasselbalch equation:

$$\text{pH} = \text{pK}' + \log \left\{ \frac{(\text{proton acceptor})}{(\text{proton donor})} \right\}$$

where $\text{pK}' = 6.86$ at 25°C.
