Hypothesis Testing in Biomedicine Rikard Johansson, 2017-10-03 The utilization of mathematical tools within biology and medicine has traditionally been less widespread compared to other hard sciences such as physics and chemistry However an increased need for tools such as data processing bioinformatics statistics and mathematical modeling have emerged due to advancements during the last decades These advancements are partly due to the development of high throughput experimental procedures and techniques which produce ever increasing amounts of data For all aspects of biology and medicine these data reveal a high level of inter connectivity between components which operate on many levels of control and with multiple feedbacks both between and within each level of control However the availability of these large scale data is not synonymous to a detailed mechanistic understanding of the underlying system Rather a mechanistic understanding is gained first when we construct a hypothesis and test its predictions experimentally Identifying interesting predictions that are quantitative in nature generally requires mathematical modeling This in turn requires that the studied system can be formulated into a mathematical model such as a series of ordinary differential equations where different hypotheses can be expressed as precise mathematical expressions that influence the output of the model Within specific sub domains of biology the utilization of mathematical models have had a long tradition such as the modeling done on electrophysiology by Hodgkin and Huxley in the 1950s However it is only in recent years with the arrival of the field known as systems biology that mathematical modeling has become more commonplace The somewhat slow adaptation of mathematical modeling in biology is partly due to historical differences in training and terminology as well as in a lack of awareness of showcases illustrating how modeling can make a difference or even be required for a correct analysis of the experimental data In this work I provide such showcases by demonstrating the universality and applicability of mathematical modeling and hypothesis testing in three disparate biological systems In Paper II we demonstrate how mathematical modeling is necessary for the correct interpretation and analysis of dominant negative inhibition data in insulin signaling in primary human adipocytes In Paper III we use modeling to determine transport rates across the nuclear membrane in yeast cells and we show how this technique is superior to traditional curve fitting methods We also demonstrate the issue of population heterogeneity and the need to account for individual differences between cells and the population at large In Paper IV we use mathematical modeling to reject three hypotheses concerning the phenomenon of facilitation in pyramidal nerve cells in rats and mice We also show how one surviving hypothesis can explain all data and adequately describe independent validation data Finally in Paper I we develop a method for model selection and discrimination using parametric bootstrapping and the combination of several different empirical distributions of traditional statistical tests We show how the empirical log likelihood ratio test is the best combination of two tests and how this can be used not only for model selection but also for model discrimination In conclusion mathematical modeling is a valuable tool for analyzing data and testing biological hypotheses regardless of the underlying biological system Further development of modeling methods and applications are therefore important since these
