

Keystone Species

Saguaro Cactus

What is a keystone species?

A keystone species is a species that has a disproportionately large effect on its environment relative to its abundance. The concept was developed by ecologist Robert H. Paine in 1969, based on his studies of the Pacific Northwest intertidal community.

Keystone species often play a critical role in maintaining the structure of an ecological community, affecting many other organisms in the ecosystem without being directly consumed by them. They are often the most important species in an ecosystem, and their removal can lead to a dramatic change in the ecosystem's structure and function.

Why is the Saguaro a keystone species?

The Saguaro cactus is a keystone species because it provides a critical habitat for many other organisms in the desert ecosystem. It is a source of food for many animals, including birds, lizards, and snakes. It also provides a place for many animals to hide from predators. The Saguaro cactus is also a source of water for many animals, and it plays a role in the water cycle.
