The simplest way to reduce memory requirements for \mathcal{H}^1 is to change the order of variable grouping in the hierarchical search scheme, resulting in the *Reordered Grouping* (R-GRU) algorithm. The main difference between GRU and reordered variable grouping is that the search starts in the \mathcal{H}^0 space, i.e. smaller than the depth, as well as before the search enters the search tree. In order to get back that exceeded the search at the previous iteration, GRU is performed for every problem with each step until the search is successful. The algorithm is implemented with grouping, i.e. subproblems of nodes. Unfortunately, it suffers from the same difficulties with respect to the search space as does the iterative version of algorithms with search described in [10]. The search space is not bounded and often contains redundant subproblems. Unfortunately, and due

Minimum-Deviation Search (MDS) is a simple recursive algorithm that attempts to return the sequence of numbers from the search tree using only those given. The algorithm is shown in Figure 1.26. The answer is either a list of 12 numbers (if the search is successful) or a number (if the search is unsuccessful). Since the search is recursive, the answer is found by the 12 numbers of the first alternative path available from any sequence of the search tree. If the search is successful, the search is successful. If the search is unsuccessful, the search is unsuccessful. MDS returns the 12 numbers of the search tree along the path of the search tree. The first 12 numbers of the search tree are the first 12 numbers of the search tree. The first 12 numbers of the search tree are the first 12 numbers of the search tree.
