How does the membrane potential ($\Delta\psi$) and the H^+ gradient make ATP during cellular respiration?

What?

The synthesis of cellular respiration is oxidative phosphorylation. Both the electron transport chain and chemiosmosis make by oxidative phosphorylation. During this phase of cellular respiration, about 34 NADH and FADH_2 have been produced in other phases of cellular respiration. Together, the two work together and chemiosmosis are used to make ATP. The process occurs inside the mitochondria in the inner mitochondrial membrane.
